Title:	UTN #50 Additions
Date:	2025-01-22
Action:	To be considered by CJK & Unihan WG and UTC

Based on the public review issues reported by Judith Chen, Andrew West (see [section 12 of L2/24-067](#)) and Eiso Chan (see [section 4 of L2/25-009](#)), this document proposes to add some additional information to UTN #50. (FYI, the document [reconstructed KPS 10721](#) was updated to the 6th version on 2025-01-17)

According to the 勘误 section and the 附录一 section in the reconstructed KPS 10721 document, there are many suboptimal mappings for KP-source characters. A small part of them were reported by Judith Chen and Andrew West as mentioned in the first paragraph of this document. Here, I will list the table with some additional comments, and propose to add the table to the excel file of UTN #50 as Sheet 2. The excel version of this table (without the comments) is attached in this proposal, and I recommend the CJK & Unihan WG to review all the characters with the comments to decide whether they should be added to UTN #50 and whether additional comments are needed for UTN #50.

Table 1. Suboptimal Mappings

	KP1 codepoint	current Unicode	better Unicode	comments
卍	KP1-3413	4E17	2000D	<i>reported by Judith</i>
嬰	KP1-3DB4	217EE	5A90

Also, there are some glyph issues in the KP-source glyphs. We do not have the right to revise any of the glyphs since we are not delegates from DPRK; however, among them, there are some identical shapes on different codepoints, which may need to be recorded in UTN #50. One of them was reported by Eiso Chan as mentioned in the first paragraph of this document.

According to the proposals from DPRK to IRG in early years, they use CheongPong V3.0 for the KP0-source characters. Actually, CheongPong V3.0 could be downloaded everywhere on the internet, we can easily see what the glyphs look like in that font, but the main problem is that DPRK did not authorize Unicode to use that font for KP-source representative glyphs, since all the KP0-source characters are included in KPS 10721 (aka KP1), so the KP1-font is used in CodeCharts instead currently.

KP1-3A3A and KP1-5565

55A3
 口 30.9
 煦 煦 煦 煦 煦 煦
 G3-5062 HB2-D872 T2-3A56 J1-3571 K1-7461 KP1-3A3A

24275
 火 86.8
 煦 煦
 GHC KP1-5565

The issue of this character is that, semantically, its radical could be both 口 and 火 – according to *Kangxi Dictionary*, it is both a variant of 煦/吹 (meaning “blow”) and a variant of 煦 (meaning “warm”). *Kangxi Dictionary* listed it under the radical 口, but according to the glyph itself, people may probably think that its radical should rather be 火. This may be the main reason why U+55A3 and U+24275 are currently (Unicode 16.0) under different radicals even they are cognate. Also, KP1-3A3A is under the radical 口 while KP1-5565 is under the radical 火 according to KPS 10721. From the viewpoint of KPS

10721, it may just be a duplicate character caused by negligence. Since we could do nothing on the glyph, and meanwhile 火 & 灬 are even NUCV, I would like to recommend the CJK & Unihan WG to pick one of these strategies:

1. Do nothing on source references, only to record it in UTN #50.
2. Remove KP1-5565 from U+24275, and add a second radical 火 to U+55A3.

KP1-7699 (=KP0-E9B7) and KP1-769A

<p>8ABF 言 149.8</p>	<p>調 調 調 調 調 調 調</p> <p>G1-3577 HB1-BDD5 T1-6E7E J0-4434 K0-7060 KP0-E9B7 V1-673D</p>
<p>FAB9 言 149.8</p>	<p>調</p> <p>KP1-769A</p>

Since this is an issue related to KP0-source, let us just see what it looks like in CheongPong V3.0 (the KP0-font). Also, we could see the other characters with the component 周 in the KP0-font (and the KP1-font is also listed for contrast):

倜 凋 周 彫 稠 綢 調 週 雕
倜 凋 周 彫 稠 綢 調 週 雕

It is clear that all the 周s look like 𠂇 冫 𠂇 丰 口 in the KP0-font while all the 周s look like 𠂇 冫 𠂇 土 口 in the KP1-font. Thus it is a systematic issue tentatively could not be solved unless one day we get the permission of using the KP0-font for KP0-source characters in CodeCharts.

KP1-8833 and KP1-8834 (=KP0-FBFD)

<p>98EE 食 184.4</p>	<p>飲</p> <p>GE-544E</p>	<p>飲 飲 飲</p> <p>J0-5D3B K0-6B66 KP0-FBFD</p>
<p>98F2 食 184.4</p>	<p>飲 飲 飲 飲 飲 飲 飲</p> <p>G1-527B HB1-B6BC T1-6323 J0-307B K6-1078 KP1-8833 V1-6C2B</p>	

This is also a similar issue as 調 mentioned above. It is a systematic issue for the component 食. Let us just see some examples:

飢飭飲飯飴飼飽飾餃餉
飢飭飲飯飴飼飽飾餃餉

All the components 食 are designed in an Older Form (something called 旧字形 in Chinese or 旧字体 in Japanese) in the KP0-font, while the same components are designed in a Newer Form (something called 新字形 in Chinese or 新字体 in Japanese). It is really a tricky issue since 飲 and 飲 were encoded separately due to the historical legacy issue. Again, nothing could be done unless one day we get the permission of using the KP0-font for KP0-source characters in CodeCharts.

KP1-3861 (=KP0-E6C5) and KP1-3862

52FA 勺 20.1 勺 勺 勺 勺 勺 勺 勺
G0-4957 HB1-A463 T1-4444 J0-3C5B K0-6D43 KP0-E6C5 V1-4D52
FA77 勺 20.1 勺
KP1-3862

Again an issue similar to 調, but more complicated since the 勺 components are inconsistent within the KP0-font:

勺杓灼的約芍葯豹酌釣
勺杓灼的約芍葯豹酌釣

The KP1-font designs the characters with the component 勺 more consistent, which leads to an issue that the glyph for U+52FA becomes identical to U+FA77. Actually, the original KP1-font extracted from the Android application named “Okpyon” does have the 勺 shape, which has to be mapped to U+FA77 (i.e. two shapes swapped). The glyph for U+FA77 was not updated because we wanted to make the KP-source glyphs from the early versions of the Unicode Standard stable – the same issue also occurs for U+FA96 and U+FA99, just as mentioned in the 1st subsection of the 勘误 section in the reconstructed KPS 10721 document. Since we do have the 勺 shape in the KP1-font (although

not used in CodeCharts currently), we do not need to “revise” the glyph, I would like to recommend the CJK & Unihan WG to pick one of these strategies:

1. Do nothing on glyphs, only to record it in UTN #50.
2. Change the representative glyph of either U+52FA or U+FA77 to 勻.

KP1–62C7 and KP1–9285

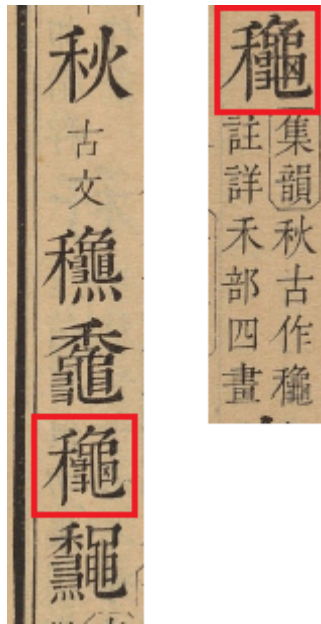

<p>418B 禾 115.16</p>							
	<p>T7-584C JMJ-030162 K3-2D61 KP1-62C7</p>						
<p>9F9D 龜 213.5</p>	<p>G5-5B33</p>						
	<p>T3-5E47 J0-6354 K1-7045 KP1-9285</p>						
<p>9F9C 龜 213.0</p>							
	<p>G1-396A HB1-C074 T1-733F J0-737D K0-4F4F KP0-D1B7 V2-9171</p>						

This is the last one, and the most complicated one. It seems that the J–, K– and KP–source glyphs on U+418B should be on U+9F9D (the glyphs for U+9F9C are listed for reference).

For J–source, after checking the update record of Moji Jōhō (aka JMJ), JMJ–030162 was initially on U+9F9D. There were many different glyphs on U+9F9D in JMJ, JMJ–030162 is later moved to U+418B, and all the remaining ones were later registered in IVD. Thus we may just say that, JMJ noticed the unused codepoint (U+418B) and recycled it for one of the variants on U+9F9D to share some pressure. Since it is intended, meanwhile unifiable, we may just ignore its existence.

For K–source, the two glyphs on the two codepoints are even EXACTLY the same. It is strange but I do not know how to explain, maybe we have to ask the Korean experts.

Let us see the most important one, also the main subject of this document, the KP–source. Let us check the *Kangxi Dictionary* first:

Some minor differences of the two glyphs could be seen. The left one is under the radical 禾 in *Kangxi Dictionary*, while the right one is under the radical 龜. As expected, U+418B is under the radical 禾 while U+9F9D is under the radical 龜, and the glyph differences of KP1-62C7 and KP1-9285 exactly matched the differences from *Kangxi Dictionary*. Actually there are so many similar cases from *Kangxi Dictionary* but they are all encoded as compatibility ideographs except for this one. Personally I do not have a strong opinion on how to deal with this pair (since we cannot move anything to a new codepoint in the compatibility block), if any from other people, please put forward, otherwise simply record it in UTN #50 would be enough.

(End of document)
